Context

Explosion in the use of LLMs

- • • • Models such as ChatGPT, LLaMA, and Mistral are widely used to generate text, code, translate, and automate tasks.

Each request seems “immaterial,” but consumes energy and emits CO₂.

A hidden environmental cost

- LLM inference requires high computing power (GPUs, servers),
→ therefore high electricity consumption.
- Electricity consumption → CO₂ emissions, depending on the energy mix (coal, gas, renewable, etc.).
- Users and businesses have virtually no visibility into the environmental impact of their queries.

Google

Meta

aws

Many proprietary models do not publish their inference data publicly and transparently (e.g., exact hardware, model version, infrastructure, energy mix, etc.).

Microsoft

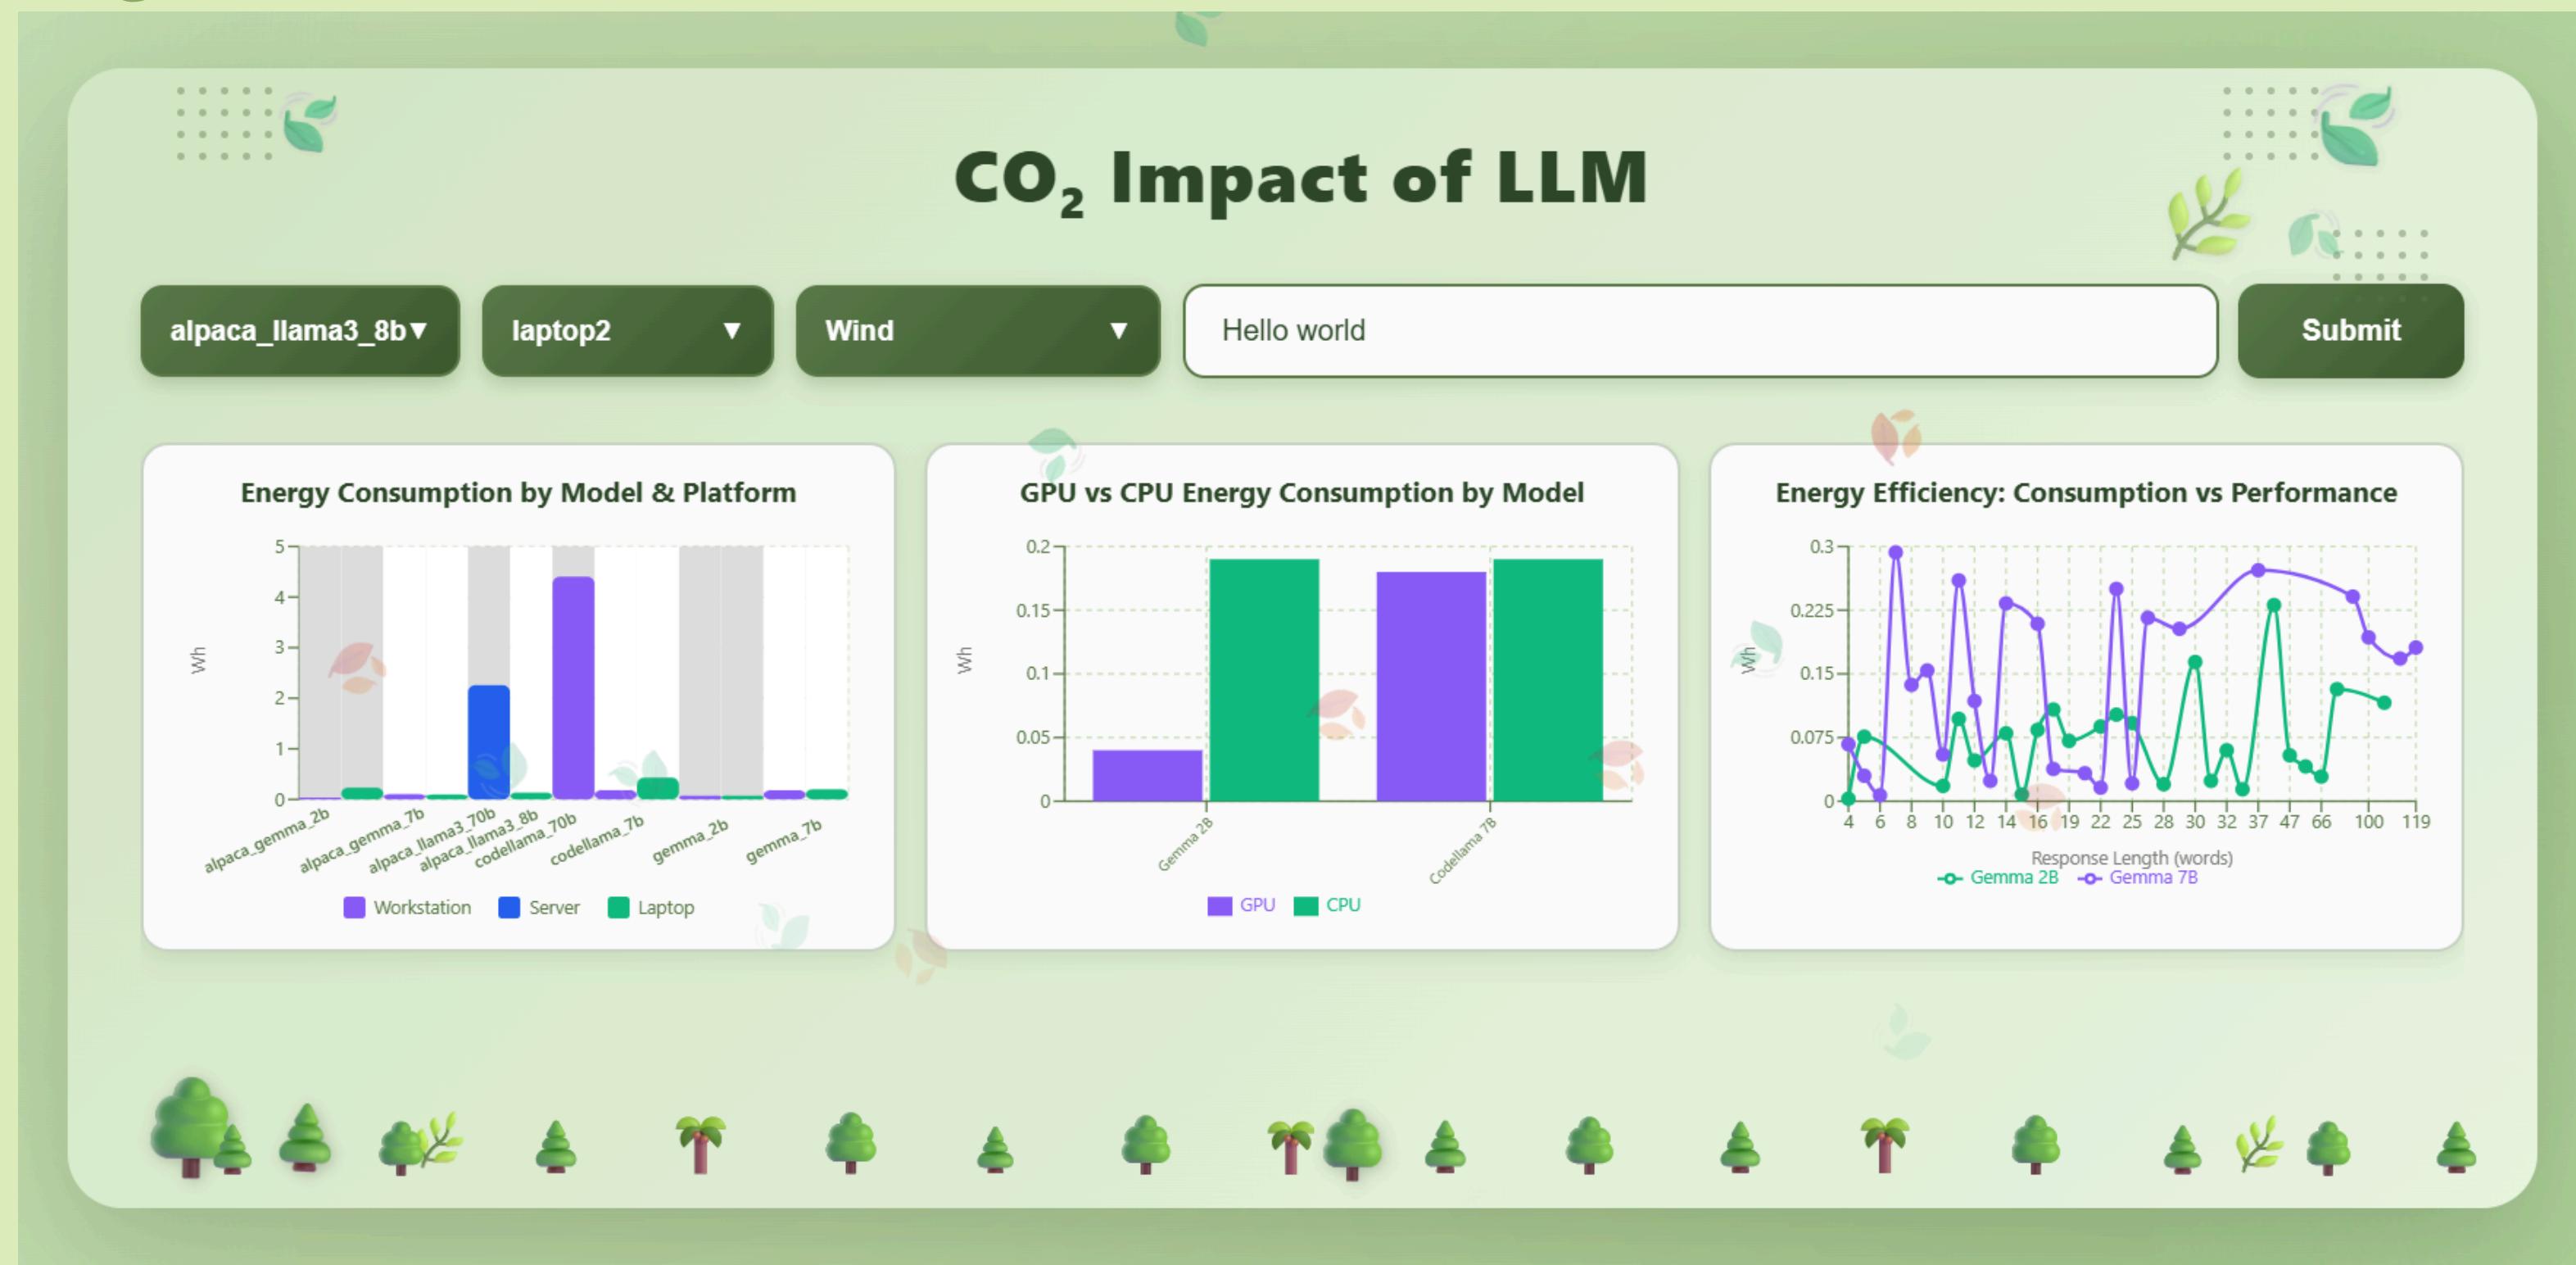

Current issues

- How much CO₂ does a single query to an LLM actually emit?
- Does this vary depending on the model (LLaMA, Falcon, etc.), the device (laptop vs. server), or the size of the query?
- How can this impact be made understandable and comparable to the real world (airplanes, smartphones, water, etc.)?

Our solution

Graphs interface with visual representations of the dashboard

Our solution

Interface with query, consumption and comparisons

The screenshot shows a web application interface with a light green background decorated with small leaf icons. At the top center, the title **CO₂ Impact of LLM** is displayed. Below the title is a search bar containing the text "Hello, how are you ?". To the left of the search bar are three dropdown menus: "alpaca_gemma_2b▼", "laptop1 ▼", and "Solar ▼". To the right of the search bar is a "Submit" button.

The main content area features a large central box labeled **CO2 Consumption** with the value **1.716 mg CO₂**. Below this are three comparison cards:

- 0.840%** of a smartphone charge (Icon: smartphone)
- 0.252 min** of LED lighting (Icon: lightbulb)
- 2.70s** of tree absorption (Icon: tree)

Each card includes a source reference: "Source: Next Business Energy" for the smartphone, "Source: Solar Technologies" for the LED lighting, and "Source: ForTomorrow, Viessmann" for the tree absorption.

Technical Approach

Data Preparation

Merged all available datasets into **one unified dataset**.

Created binary columns (one-hot encoding) for each LLM model and hardware type.

Kept only features that depend solely on the user prompt, not on the generated output
→ to allow prediction before inference happens.

Selected Input Features

- **Prompt-related textual features :**

word_count, sentence_count, avg_word_length, unique_word_count, avg_sentence_length, punctuation_count, long_word_count, verb_count, monosyllabcount

- **Task type (classification of the prompt) :**

task_alpaca (instruction-following), task_codefeedback (coding-related request)

- **LLM model used :**

model_codellama_7b, model_codellama_70b, model_gemma_2b, model_gemma_7b, model_llama3_8b, model_llama3_70b

- **Hardware type (execution environment) :**

hardware_laptop1, hardware_laptop2, hardware_workstation, hardware_server

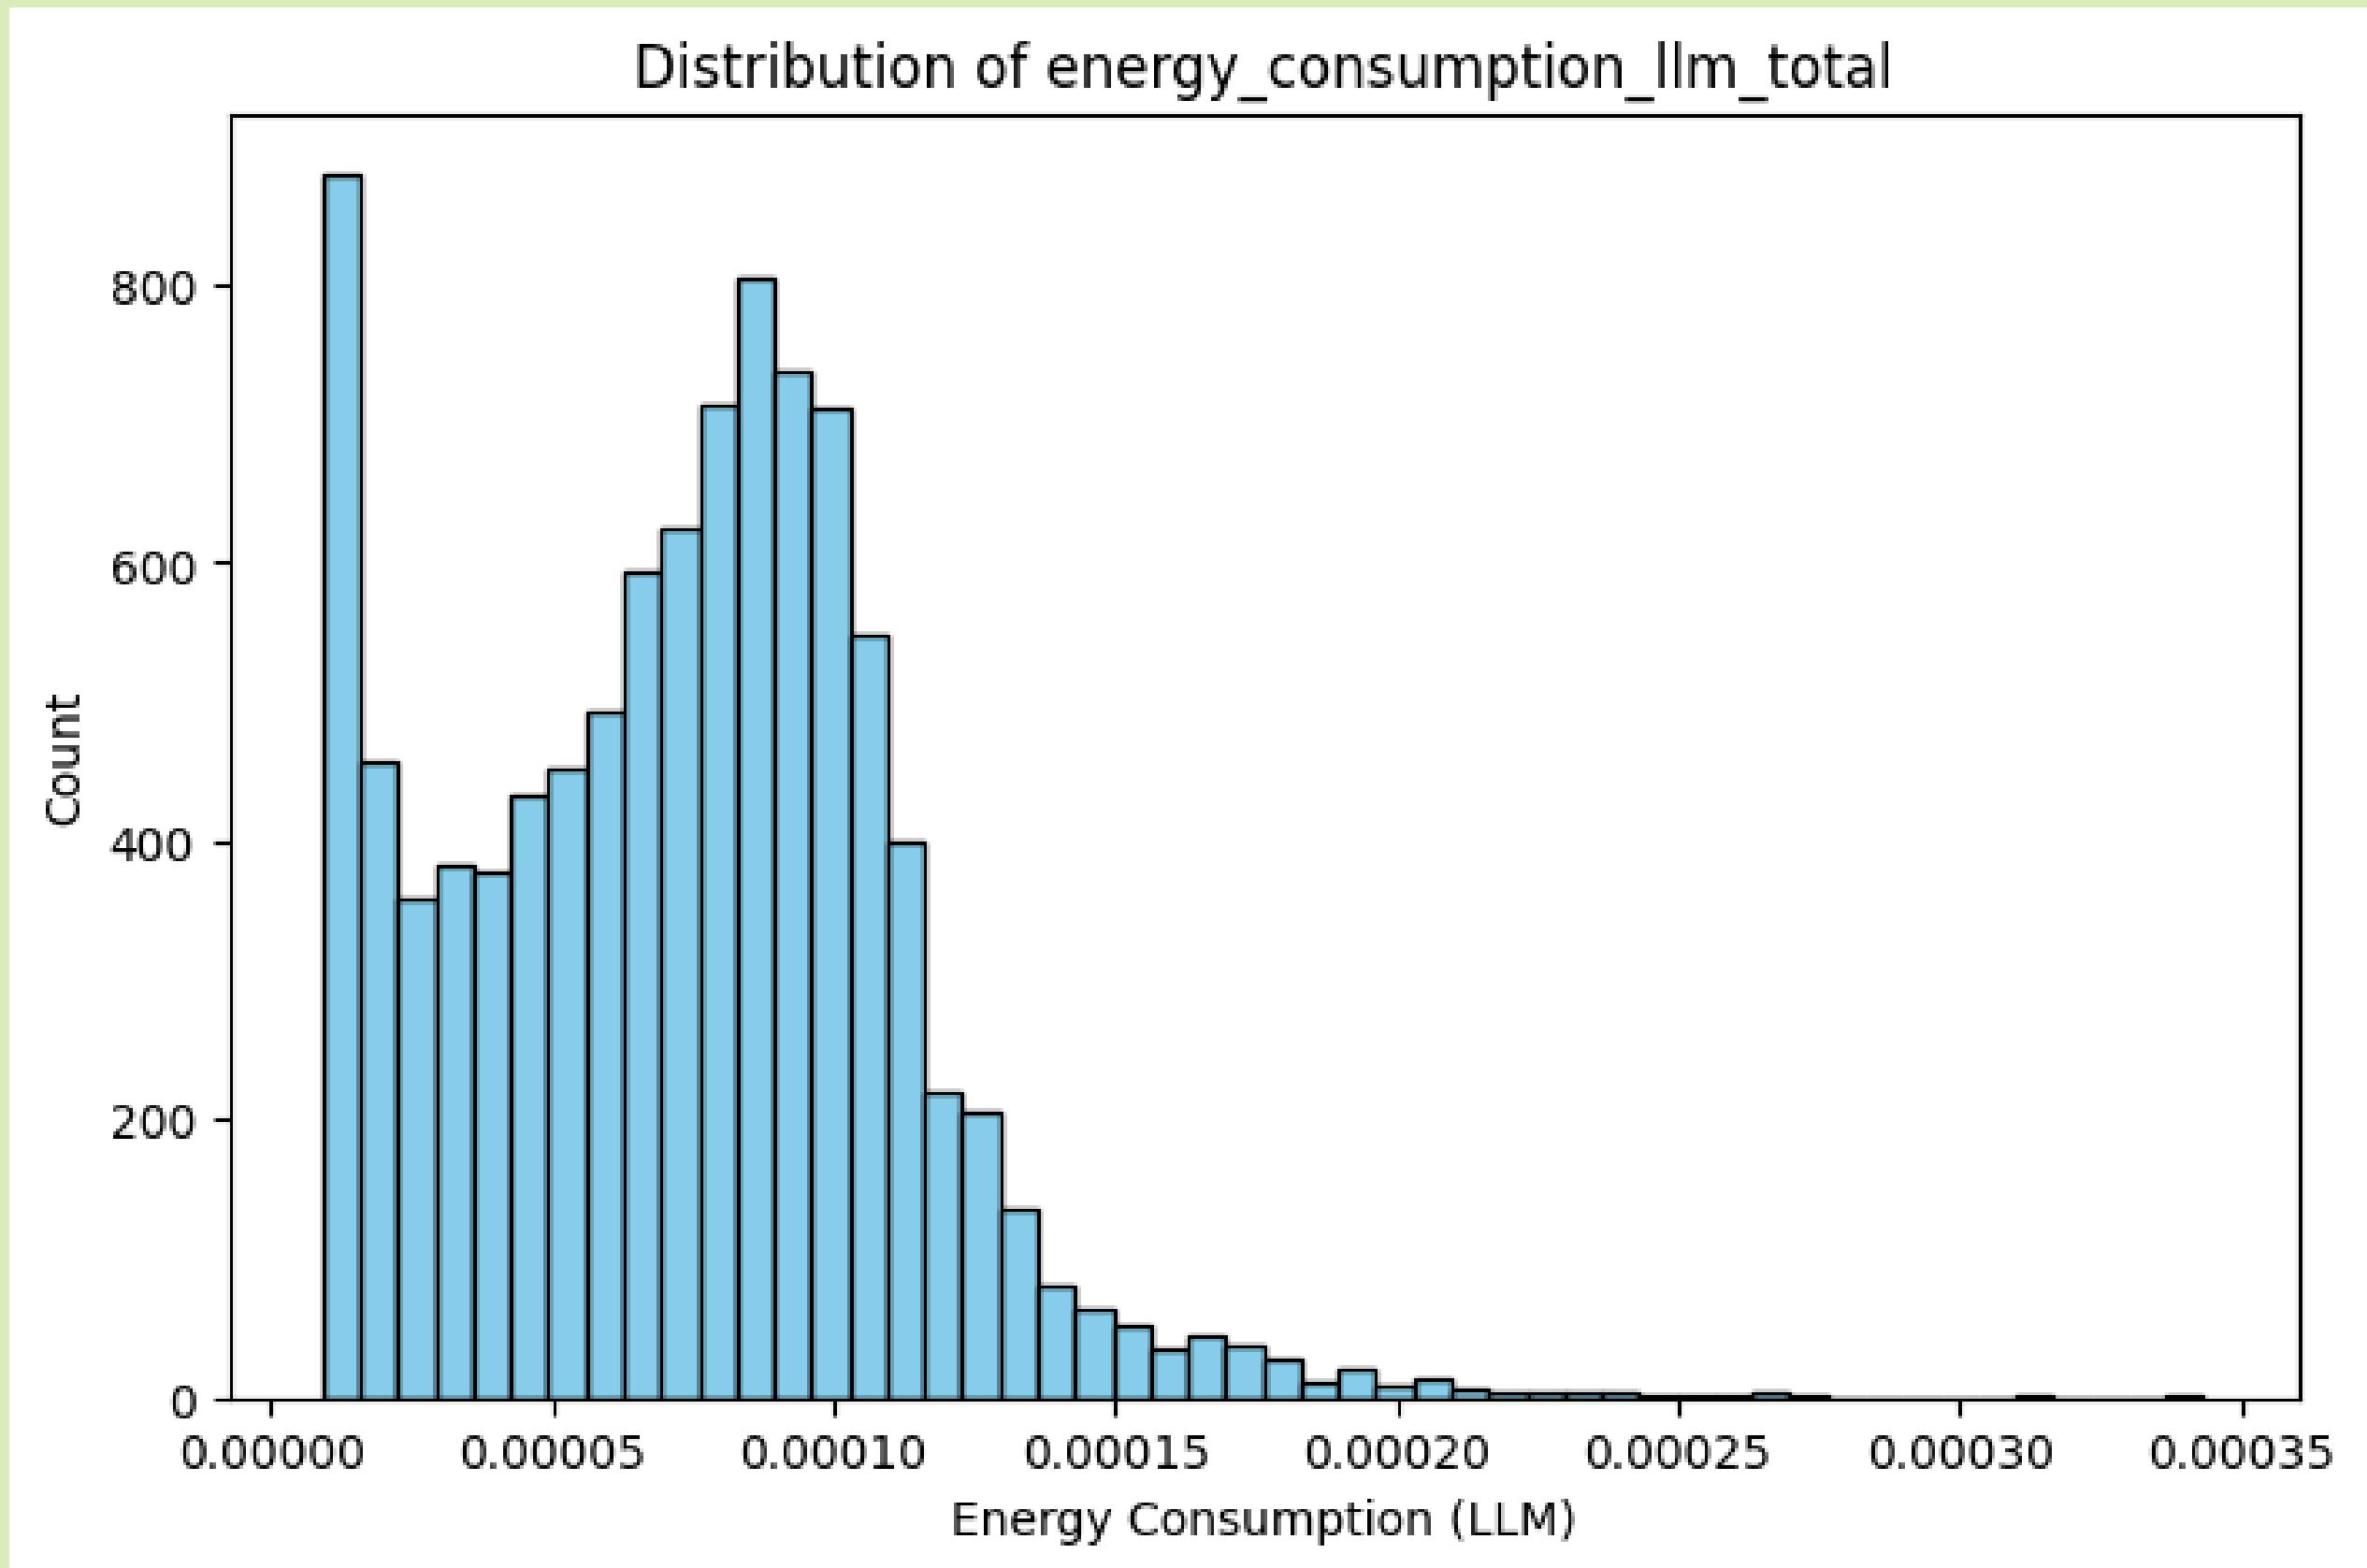

Model Training

Machine Learning model used: **Random Forest Regressor**

Trained on the entire dataset with these selected features.

Target variable predicted: Energy consumption per request (Wh) → later converted to CO₂ emissions (gCO₂e).

Technical approach

Our solution

A simple interface to make the invisible carbon impact of each AI query visible

A solution designed with the end user in mind

No technical knowledge required (GPU, tokens, energy, etc.)

Minimalist UX interface

A clear, simple, and powerful output

CO₂ score generated by the request

Immediate visualization + interpretation with comparison cases

Graphs with visualisation of the dashboard used for training of the platform

Why is this significant ?

- Makes an invisible subject → visible
- Transforms technical data into concrete & memorable comparisons
- Enables everyone to become aware in two clicks and adopt more responsible usage
- Accessible to individuals, students, businesses → democratization of sustainable AI

Our vision for the future

Our goal is not to stop AI but it's to make it sustainable.

Smarter and greener AI models

Use our results to optimize models: reduce energy consumption without compromising performance.

Create a “Green Ranking” of the most efficient LLMs (performance vs. CO₂).

Integration into real-world tools

Provide a public API: integrable into VS Code, Hugging Face, websites, enterprise dashboards, etc.

Enable companies to track their AI emissions in real time.

Personalized recommendations for eco-friendly AI

Offer users:

- “This model generates the same response, but consumes 3× less energy.”
- “Use this hardware or cloud region to reduce the impact by 40%.”

Thank you for your attention
